## THESIS

---

---

## CENTRAL CLAIM:

The word embeddings used in NLP algorithms have consistently demonstrated gender bias. While there are new methods for debiasing these embeddings, they aren't effective enough since they hide bias, rather than actually removing it.

---

# 02

## CURRENT DEBIASING METHODS

---

# METHOD 1

## HARD DEBIASING

- Post processing debiasing method - manipulates vectors after training.
- Makes neutral words equidistant from gendered ones.
- Removes the gender direction from neutral words.

# METHOD 2

## GN-GloVe

- Aims to debias word embeddings **during** training.
- Changes the **loss** of the model.
- Uses 2 groups of f/m words and makes them **differ in the last coordinate** -> that's the key idea.
- This allows to **exclude** the last coordinate.
- Representation of neutral words is **orthogonal** to the gender direction -> their dot product should be 0.

## THE MAIN PROBLEM:

Saying that a word is “debiased” when it is only equidistant from two gendered words is inadequate. This is because even when this is true, words associated with certain gender stereotypes will cluster together.

\*\*\*Both of these methods use this definition\*\*\*

Most frequent words

47,698

Words for GN-GloVe

26,189

Words for Hard-Debiased

## Setup

Bias of a word is computed by taking its **projection** on the **gender direction**.

Association between sets of words is quantified using WEAT (estimating the probability that a random **permutation** of the target words, e.g. professions, would be **close** to the attributes sets).

## Experiments

**500** most biased words from each group were clustered using k-means, then accuracy of **alignment** with gender was computed for both of the embeddings.

It was suggested to measure bias by approximating the **percentage** of f/m words among k nearest **neighbors** of the target word, it was implemented for a list of professions.

**Correlation** between this and the original measure was computed.

Predicted the **gender** and evaluated its **regularization** on the remainders using an RBF-kernel SVM.

## RESULTS

---

# RESULTS (CNTD)

## CLUSTERING

male and female  
biased words cluster  
together. (High  
percentage of  
alignment)

## CONCLUSION

When clustering is considered in the definition of  
bias, these embeddings are still fairly biased after  
debiasing.

## BIAS PRESENT

High accuracy of  
predicting gender of  
debaised words based  
on most biased  
words.

## ASSOCIATIONS

Association found  
between female/male  
concepts and  
stereotyped words

# 05

## CONCLUSION

# DISCOVERIES

Words with strong initial gender bias are easy to cluster together even after “debiasing”.

**1.**

Words that receive implicit gender from social stereotypes tend to group with other such words of the same gender.

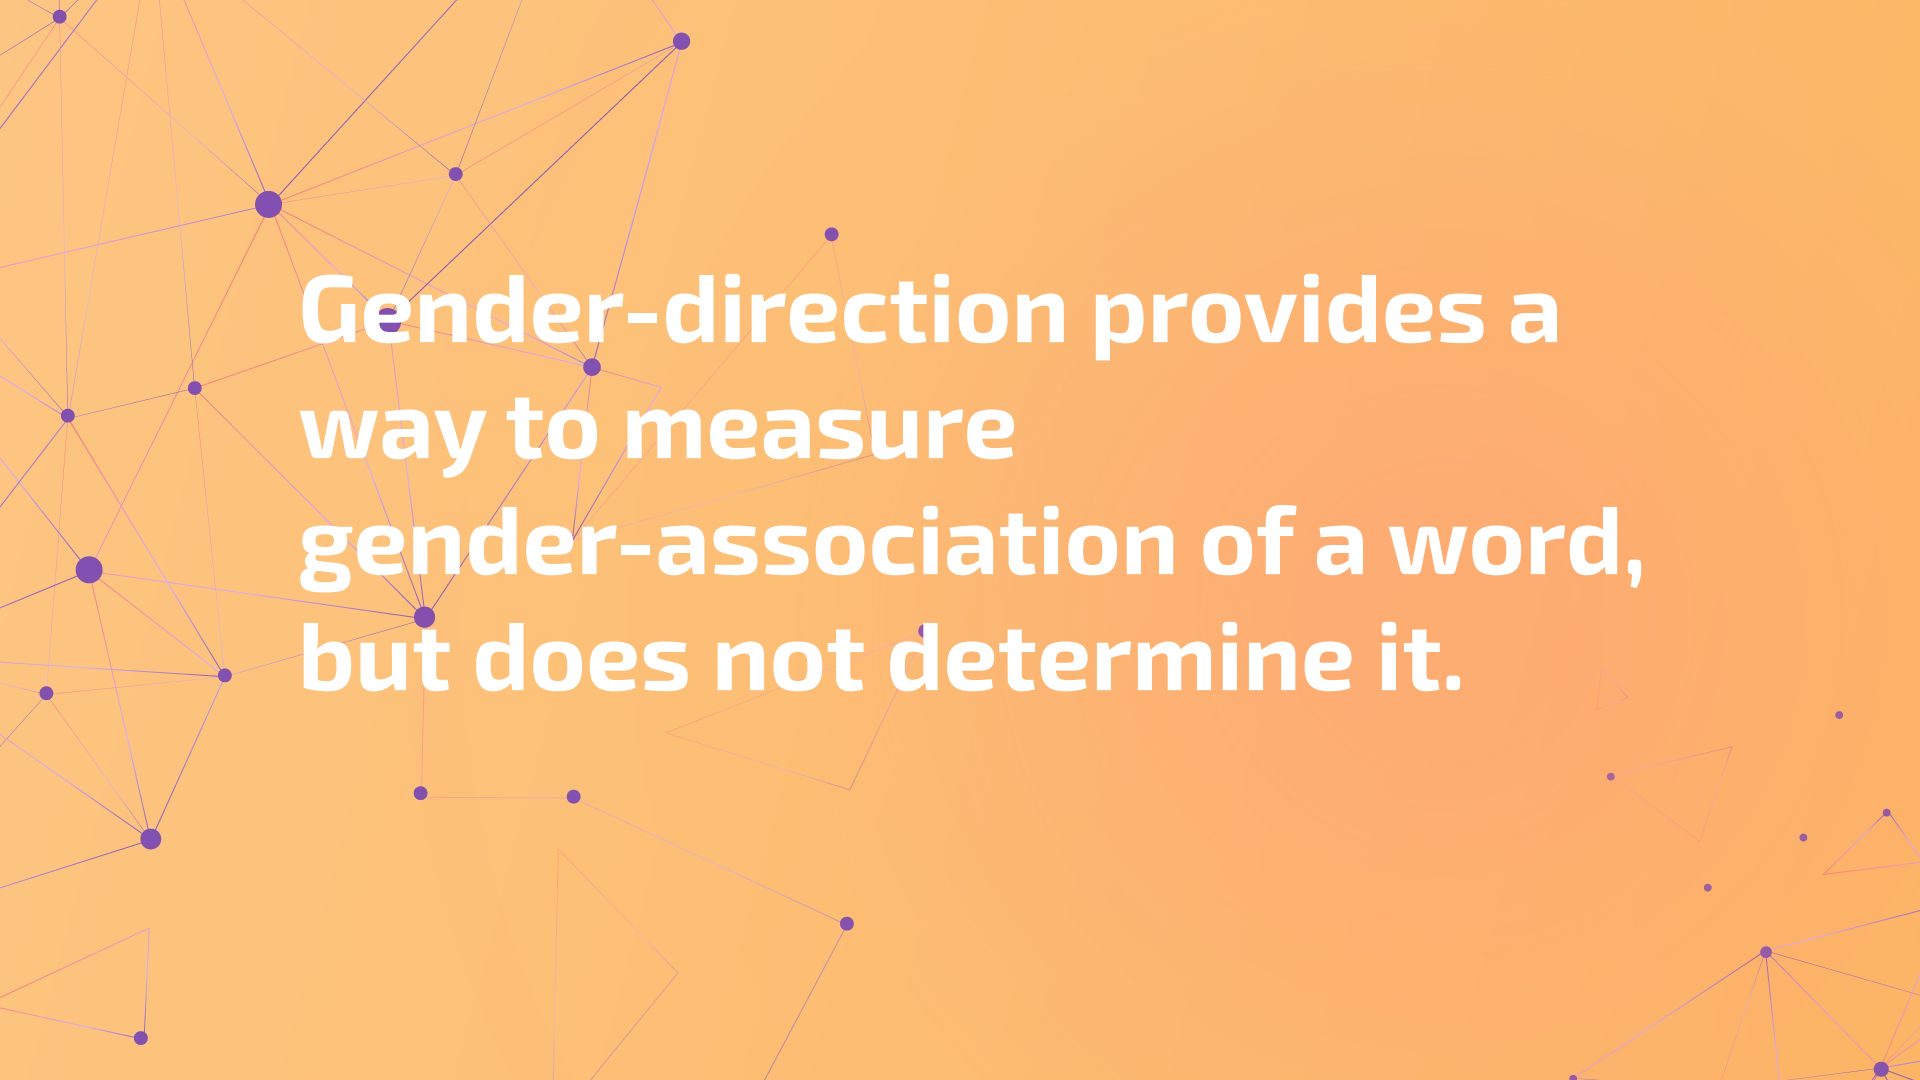

**2.**

The implicit gender of words with prevalent previous bias is easy to predict based on their vectors alone.

**3.**

The background of the slide is a solid orange color. Overlaid on this background is a complex network of thin, light purple lines connecting various-sized purple dots. Some dots are larger than others, and the lines form a web-like structure that is denser on the left side and more sparse on the right. The text is centered in the middle of the slide, written in a bold, white, sans-serif font.

**Gender-direction provides a way to measure gender-association of a word, but does not determine it.**

The background is a solid orange color. On the left side, there is a complex network of thin purple lines connecting various-sized purple dots. Some dots are larger than others. This network forms a series of interconnected triangles and polygons. A few more isolated dots and small line segments are scattered on the right side of the slide.
